

Silver-Beaked Tanagers (*Ramphocelus carbo*) are known as conspicuous widespread birds. Their habitat range from Peru, Venezuela, Brazil until the Guyana's (British-Guyana, Suriname and French-Guyana).

As they are common widespread passerine birds they are certified as least concerned bird species. Silver-Beaked Tanagers feel at any level at home, from undergrowth forest edges to open civilized areas.

They like to forage in noisy small flocks (10 – 20 the least) of their own kind, but they are not shy to also join mixed flocks on their journey in search of food. They have a wide variety in taste too: insects, seeds, berries, rice, bread and fruit (banana, papaya, melon, mango ... just to name a few).

The male Silver-Beaked Tanager has a remarkable dark red appearance whenever the sun is shining right on his feathers. He is also recognizable by the visible white lower mandible (juveniles sport a grey/dark silver lower mandible), earning him the name Silver-beaked tanager.
